silk, *n.* **1.** A fine, delicate, glossy, fibrous substance produced by various insects, especially by the larvæ of bombycid moths (silkworms) to form their cocoons. The silk of commerce is obtained mostly from the common silkworm (*Bombyx mori*). In the manufacture of silk the cocoon, in which the chrysalis is killed, is placed in warm water, to soften the gum. The silk on the outside of the cocoon, called **floss-silk**, is of poor quality. If the natural gum is left on it is **hard silk**; if soaked off, **soft silk**. When the silk is first reeled into skeins and hanks it is **raw silk**. After being properly scraped and cleaned, it is ready for spinning and doubling. Before doubling the threads are known as *singles;* specifically, if wound and cleaned, *dumb singles*, and if also thrown, *thrown singles*. When twisted two or three together it is *tram*, suitable for filling. If double-twisted, it is **organzine** or **thrown silk**, suitable for warp. Silk was introduced into Europe from the East through the conquests of Alexander the Great, worn by the Romans, made largely by the Sicilians and Venetians in the 12th century, and came into common use in England in the 16th century.

A variety of machines are used in the manufacture of silk; as, **silk-degumming machine** (for removing the natural gum from silk-fiber, by mechanical action and warm water), **s.-doubling machine** (for uniting, by twisting, two or more twisted silk filaments), **s.-sizing** or **s.-sorting machine** (for sorting silk threads according to thickness and winding them on bobbins), **s.-softening machine** (for softening and polishing dyed silk-fibers by passing the skeins over reciprocating bobbins), **s.-testing machine** (for testing the tensile strength of silk-fibers—a serigraph or serimeter).

The cocoon which once gave the Lebanon *silk* its great superiority no longer exists, and has been replaced by those introduced from Japan, which are larger in size but inferior in texture.

(See GOLD.) The localities where silver occurs are numerous, including even the waters of the ocean. In 1892 the world's production was $196,605,184, of which amount the United States, the largest silver-producing country, yielded $74,389,900 (mostly from argentiferous galena), while Mexico followed with $59,000,000. In the United States, Colorado, Montana, and Nevada have been the leading silver-producing States. Like gold, it is extensively used in the manufacture of jewelry, plate, and coin. Its salts are used in photography, electroplating, marking-ink, surgery, and hair-dyes, and for many other purposes in the arts.

Synonyms: brief, delineation, draft, drawing, outline, picture, plan, skeleton. An *outline* gives only the bounding or determining lines of a figure or a scene; a *sketch* may give not only lines but shading and color, but is hasty and incomplete. The lines of a *sketch* are seldom so full and continuous as those of an *outline*, being, like the shading or color, little more than indications or suggestions according to which a finished *picture* may be made; the artist's first representation of a sunset, the hues of which change so rapidly, must of necessity be a *sketch*. *Draft* and *plan* apply especially to mechanical drawing, of which *outline*, *sketch*, and *drawing* are also used; a *plan* is strictly a view from above, as of a building or machine, giving the lines of a horizontal section, originally at the level of the ground, now in a wider sense at any height; as, a *plan* of the cellar; a *plan* of the attic. A mechanical *drawing* is always understood to be in full detail; a *draft* is an incomplete or unfinished *drawing*; a *design* is such a preliminary *sketch* as indicates the object to be accomplished or the result to be attained, and is understood to be original. One may make a *drawing* of any well-known mechanism, or a *drawing* from another man's *design*, but if he says "the *design* is mine," he claims it as his own invention or composition. In written composition an *outline* gives simply the main divisions, and in the case of a sermon is often called a *skeleton*; a somewhat fuller suggestion of illustration, treatment, and style is given in a *sketch*. A lawyer's *brief* is a succinct statement of the main facts involved in a case, and of the main heads of his argument on points of law, with references to authorities cited; the *brief* has none of the vagueness of a *sketch*, being sufficiently exact and complete to form, on occasion, the basis for the decision of the court without oral argument, when the case is said to be "submitted on *brief*." There is a tendency to restrict the application of *perfume* to the artificial preparations called collectively "perfumery." *Scent* is chiefly used for the characteristic *odor* of an animal by which it is tracked or avoided by other animals; the word is also applied to any *odor,* natural or artificial, especially when faintly diffused through the air; as, the *scent* of mignonette or of new-mown hay. *Savor* is chiefly said of the appetizing *odor* evolved from articles of food by the processes of cooking. Any *smell* that is at once foul, strong, and pervasive may be called a *stench. Socialism, as claimed by its advocates, is distinguished from *communism* in not demanding a community of goods or property, and from *nationalism* in not asking that all individuals shall be rewarded alike. *Fabianism* is a modified form of socialism that aims to bring about similar results through the Fabian policy of putting industry under state ownership only so fast as the state can be made ready to operate it.

Many socialists call themselves *collectivists*, and their system *collectivism*. *Communism* would divide all things, including the profits of individual labor, among members of the community; many of its advocates would abolish marriage and the family relation. *Anarchism* would destroy, by violence if necessary, all existing government and social order, leaving the future to determine what, if anything, should be raised upon their ruins.

—**Christian socialism**, Christianity applied to social reform, in accordance with the views of Maurice, Kingsley, and Ludlow (1848–'52). sol'id, *n.* **1.** A mass of matter of which the shape can not be changed permanently and greatly without fracture. See STATES OF MATTER, under MATTER.

It is impossible to draw a hard and fast line between solids and liquids. In physics the two are distinguished by the yielding of a liquid to any force, no matter how small, if it is only given time enough, but the same body may act as solid and as liquid to different forces. Thus, shoemakers' wax, which in common language would be called a solid, is classed by physicists as a very viscous liquid, as it will flow appreciably by its own weight in the course of several months, but it may be fractured like a solid by a sudden blow. Again, metals may be made to flow under very great pressure, like liquids. The shape of a solid can be altered only temporarily by force unless that alteration exceeds its limit of elasticity, when it becomes permanent. On the molecular theory these peculiarities are explained by supposing the molecules of solids to be describing closed curves in systems or groups, which tend to preserve their identity till a very great force causes a rearrangement of the molecules in new groups.

The latter view is called the **gaseous** or **osmotic theory of solution**, because the fact that osmotic pressures of solutions of different concentrations follow a law similar to Boyle's (see LAW) seems to support it. C., which turned attention mainly to the phenomena of the thinking and willing subject (though only in his individual character), and thus effected the transition from philosophy as a cosmology to the phase more fully developed by the Socratic school. See GREEK PHILOSOPHY. (2) A professed teacher of wisdom; one of the later Greek teachers of philosophy and rhetoric that resulted from the perversion of the principle (of individual subjectivism) of the early sophists, and in the end devoted themselves to mere frivolities. In the earlier period they claimed to give their pupils a liberal education, and especially to prepare them for civic life, regarding success in life rather than truth as the end of intellectual effort. They acquired great and pernicious skill in disputation under logical forms, especially in the use of specious and fallacious modes of thought designed to "make the worse appear the better cause," and in all kinds of quibbling and casuistry, and so brought themselves and their methods into contempt. This school was revived in the 2d century A. D. in the form of professional orators and declaimers, and later still as defenders of paganism and philosophic culture. Lucian and Julian the emperor belonged to the later schools.

It is **progressive** or **Aristotelian** when the argument descends from whole to part, and **regressive** or **Goclenian** when it ascends from part to whole. When the whole is an individual—a sum of qualities—and the parts are its qualities, the sorites is **comprehensive**; when the whole is a class, and the parts are its individual members, the sorites is **extensive**. The progressive comprehensive sorites is the same as the regressive extensive sorites, and vice versa; hence there has been some confusion in the use of the terms. The following are examples:

Progressive Comprehensive Sorites.	Regressive Comprehensive Sorites.
Bucephalus is a horse;	An animal is a substance;
A horse is a quadruped;	A quadruped is an animal;
A quadruped is an animal;	A horse is a quadruped;
An animal is a substance;	Bucephalus is a horse;
Therefore Bucephalus is a substance.	Therefore Bucephalus is a substance.

The sorites can be expanded into a compound syllogism consisting of as many simple syllogisms as there are middle terms between the subject of the first and the predicate of the final proposition.

2. A sophism of which the Stoic Chrysippus (282–209 B. C.) was reputed the inventor, in which the disputant is brought by small degrees from the admission of what seems self-evident truth to the admission of what is manifestly absurd or false: the original sense. The modern sense, as given above, arose in the 15th century A. D. **cell'max‡.**

> This sophism, as applied by Eubulides, . . . took the name of . . . : calvus, the bald. It was asked,—was a man bald who had so many thousand hairs; you answer, no: the antagonist goes on diminishing and diminishing the number, till either you admit that he who was not bald with a certain number of hairs, becomes bald when that complement is diminished by a single hair; or you go on denying him to be bald, until his head be hypothetically denuded. Such was the quibble which obtained the name of *Sorites*,—acervalis, climax, gradatio, etc. This, it is evident, had no real analogy with the form of reasoning now known in logic under the name of *Sorites*. HAMILTON *Logic* lect. xix, p. 268. [G. & L. '60.]

Materialism regards the soul as a function of the body; monism, as one phase of a substance of which matter is the

other; idealism, as the only existence, not excluding other finite souls and the Divine Being. In the Scriptures the word is used in various senses: by Christ on one occasion in emphatic distinction from the body (*Matt.* x, 28); by the apostle Paul as the *psyche*, distinguished from both body and spirit (*pneuma*).

The word *soul* differs from spirit as the species from the genus: *soul* being limited to a spirit that either is or has been connected with a body or material organization; while spirit may also be applied to a being that has not as present, or is believed never to have had, such connection. PORTER *Human Intellect* § 2, p. 6. [S. '70.]

sound[1], *n.* **1.** The sensation produced through the organs of hearing. **2.** The physical cause of this sensation: waves of alternate condensation and rarefaction passing through an elastic body, whether solid, liquid, or gaseous, but especially through the atmosphere.

In the sense of def. 1, a vibration that does not affect the ear, either because of its qualities or because no ear is within its range, causes no sound. In that of def. 2, all such are sounds, and are hence classified as **audible** and **inaudible.** All harsh, sudden sounds are called *noises*, and are due to irregular or discontinuous vibration. Sounds due to regular vibration, called **musical sounds,** possess three qualities: (1) *intensity*, due to the extent of the vibra-

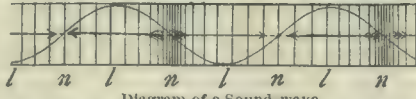

Diagram of a Sound-wave.

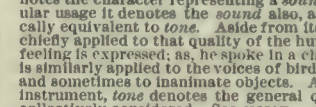
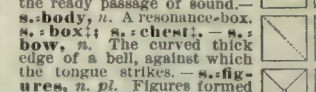
The vertical lines represent by their degree of separation the condensation or rarefaction of the medium through which the wave passes. These states of condensation and rarefaction move steadily from left to right, but the individual particles move only to and fro in straight lines. At the instant represented they are moving in the directions indicated by the arrows. The curved line shows graphically the speed of this motion by its distance above or below the horizontal line of arrows. Thus, the motion is greatest at the points *l*, and there is none at all, for the instant, at the points *n*. In a progressive wave these points move with the wave. In a stationary wave, such as that in an organ-pipe, they remain at the same places, and are then called respectively *loops* and *nodes*. Compare illus. under NODE.

tion; (2) *pitch*, due to its rapidity; and (3) *timbre*, or *color*, due to its form. The vibrations audible to the human ear range from 24 to about 40,000 a second. Sound travels at the rate of 1,090 feet a second in air, and at very variable rates in different media. Sound-waves may be reflected, refracted, and diffracted like light-waves. They may also interfere. See BEAT, 7.



3. In popular use, the vibration of some sounding body itself that produces the sound-waves that are borne to the ear. **4.** Noise of any specified quality; any tone, voice, or note having a given effect on the ear or the mind; as, a *sound* of revelry; a harsh *sound;* an appalling *sound*.



From every cliff and valley came the sweet *sound* of the Angelus bell, mingling with the tints of earth and heaven that make twilight so divine in Italy.
CHRISTIAN REID *Heart of Steel* pt. ii, ch. 21, p. 381. [A. '83.]

5. Sounding or hearing distance; ear-shot; as, to be within *sound* of a battle. **6.** Mere empty noise without signification; as, to be full of *sound* and fury. **7.** *Philol.* One of a series of articulate utterances produced by different degrees of approximation of the same organs; as, vowel *sounds*. [< F. *son*, < L. *sonus*, sound.] **soun†.**

Synonyms: noise, note, tone. *Sound* is the most comprehensive word, applying to anything that is audible. *Tone* is *sound* considered as having some musical quality or as expressive of some feeling; *noise* is *sound* considered without reference to musical quality or as distinctly unmusical or discordant. Thus, in the most general sense *noise* and *sound* scarcely differ, and we say almost indifferently "I heard a *sound*" or "I heard a *noise*." We speak of a fine, musical, or pleasing *sound*, but never thus of a *noise*. In music, *tone* may denote either a musical *sound* or the interval between two such *sounds*, but in the most careful usage the latter is now distinguished as the "interval," leaving *tone* to stand only for the *sound*. *Note* in music strictly denotes the character representing a *sound*, but in loose popular usage it denotes the *sound* also, and becomes practically equivalent to *tone*. Aside from its musical use, *tone* is chiefly applied to that quality of the human voice by which feeling is expressed; as, he spoke in a cheery *tone;* the word is similarly applied to the voices of birds and other animals, and sometimes to inanimate objects. As used of a musical instrument, *tone* denotes the general quality of its sounds collectively considered. See NOISE.

2. Continuous or unlimited extension, whether occupied by body or not. (1) *Math.* Continuous extension regarded as something in which objects exist and in which motion takes place.

In Euclidean geometry space agrees with our experience in having three dimensions (that is, three is the largest number of directions in it that are wholly independent of each other); it is continuous and infinite, and all parts of it have the same relations, so that bodies may change their absolute position in space without altering their positions relatively to each other. In non-Euclidean geometry these postulates are not considered as true, as, hypothetically, space may have more than three dimensions, or parallel lines may be supposed to meet, different portions of space may be considered as having different properties, or space may be regarded as limited. Though all the varieties of non-Euclidean space seem to be quite contrary to the space of our experience, it is possible that some one of them may represent it more nearly than the Euclidean if we suppose that the difference between them is so slight that it can not be detected by any means in our power.

(2) *Metaph.* (*a*) Continuous or unlimited extension considered as void of all matter or without reference to anything contained in it. (*b*) The metaphysical notion of such extension.

Touching the *nature of space*, (1) some philosophers, idealists, hold it to be purely ideal and without any objective reality, it being merely a subjective condition of sensibility or sensible experience (Kant, etc.); (2) others regard it as an objective reality, either (*a*) an actual entity, which, though not an object of sense, is a necessary concomitant and condition of sense-experience, the void or vacuum containing all things (the popular view); or (*b*) an actual relation, the order of coexistent phenomena (Leibnitz); (3) still others hold it to be both ideal and objective, the plan of the world corresponding with that of the mind (Scottish philosophers). Touching the origin of the *notion of space*, (1) transcendentalists hold that it is strictly intuitional, originated by the mind itself independent of and prior to experience; (2) experientialists hold it to be strictly the product of experience; (3) the common-sense philosophers hold it to be a product of intuition evolved always in connection with and consequent upon experience.

4. *Elec.* Properly, the luminous effect of a disruptive discharge, or the discharge itself (see DISCHARGE), especially when its ramifications are not numerous enough to be called a brush; loosely, a small transient arc or an incandescent particle thrown off from such an arc.

The length of the true spark varies with the difference of potential of the conductors between which the discharge takes place, and with the nature and density of the separating medium. It can not pass in a very rare medium. Its light is due chiefly to incandescence of the medium in the path of the discharge.

The *spark* discharge is the brilliant line of light which marks the breaking down of the dielectric and the total transfer of the electrification through it. When the thickness of the dielectric is not great, the *spark* is straight, but as the distance increases, its path becomes irregular, due to compression of the air in its front. The volume of the *spark* increases with the quantity of electrification transferred. G. F. BARKER *Physics* p. 320, p. 615. [H. H. & CO.]

In England the Lord Chancellor is ex officio presiding officer or Speaker of the House of Lords. Unless he is in his own right a peer of the realm, he is not a member of that house, and has no right to speak or vote, nor even to give a casting vote; in case of a tie vote the motion fails. In the House of Commons the Speaker is elected by the members, with the approval of the crown, and is himself a member, and holds the office throughout the continuance of that house. He may give a casting vote in case of a tie, but never votes otherwise. In the United States, in case of absence or disability of the Speaker, a member is chosen to act for the time being, called *Speaker pro tem.* In England one so serving is called *deputy Speaker*, and in the House of Lords he is appointed by the crown.

The *Speaker's* distribution of members among the committees is, next to his own election, the most critical point in the history of a Congress. . . . In explaining the process of external perception, or how we come to the knowledge of things out of and distant from us, it was maintained that these objects send forth *species* or images of themselves, which, making an impression on the bodily organs, next imprinted themselves on the mind and issued in knowledge. The *species* considered as the vicarious representative of the object, was called intentional. And as it affected both the intellect and the sense, was distinguished as sensible and intelligible. Specific qualities may be expressed in two ways: (1) By comparison with the same quality in some substance arbitrarily assumed as a standard. Thus, the specific gravity of a substance is the weight of any volume of it compared with that of an equal volume of water; the specific inductive capacity of a dielectric is its inductive capacity relative to that of air; the specific resistance of a conducting substance is the resistance of any piece of it in terms of the resistance of an exactly similar piece of silver. (2) By stating the absolute measure of the quality in a standard amount of the substance. Thus, the specific resistance of a substance may be given as the resistance in absolute measure of a cubic centimeter of the substance.

spec′tro-scope, *n. Physics.* An optical instrument for forming and analyzing the spectra of the rays emitted by bodies or substances: invented by the German chemists Gustav Kirchhoff and Robert Bunsen, about 1859.

Spectroscopes consist in general of three essential parts: (1) that through which the light is admitted, consisting usually of a collimating-tube bearing at its end a slit of adjustable width, and containing lenses for making the admitted rays parallel; (2) that in which dispersion takes

place, forming the spectrum, as a prism, a train of prisms, or a diffraction grating; and (3) a small telescope through which the observer views the spectrum, and which can be moved to view different orders of spectra or different parts of the same spectrum. In addition, there is usually a device for the measurement of the spectrum, as by throwing upon it the image of a minute scale. Usually, owing to the deviation of the light by the prism, the collimating- and observing-tubes of a refracting spectroscope make a considerable angle with each other, but in a form often portable) called the **direct-vision spectroscope** all these parts are contained in a single straight tube, the train of prisms being composed of different kinds of glass so arranged that deviation is corrected, but not dispersion. If a Rowland concave grating is used, no observing-telescope is necessary, the grating forming a real image, which may be received on a screen or a photographic plate, or viewed with a simple eyepiece. The resulting spectrum may be so long that the eyepiece must be mounted on a carriage that travels along a miniature railway. For the uses of the spectroscope, see SPECTRUM ANALYSIS.

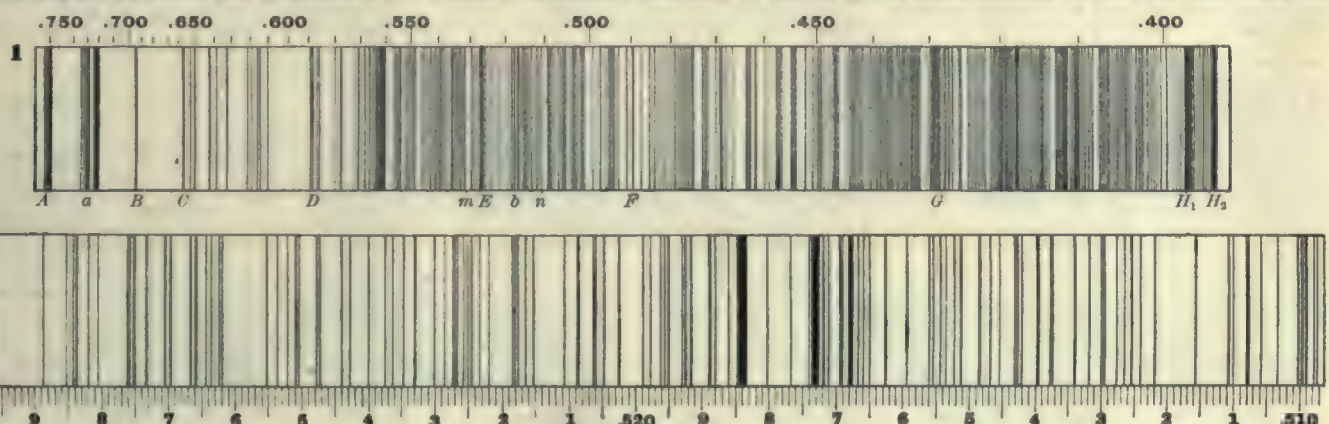
spec'tro-sco"py, spec'tro-sc5'pi, *C. W.*[2] (spec-tros'co-pi, *W.*[1]) (XIII), *n.* The branch of physical science that treats of the phenomena observed with the spectroscope, or those principles on which its action is based; also, the art of using the spectroscope; spectrum analysis.

Since the science of *spectroscopy* . . . has attained so high an importance in connection with investigations . . . the spectrum has been photographed upon a much larger scale than was attempted by Dr. Draper. F. A. P. BARNARD *First Century of the Republic* ch. 11, p. 319. [H. '76.]

spec'trum, spec'trum, *n.* [SPEC'TRA, *pl.*] **1.** *Physics.* An image, visible or invisible, formed by rays of light or other radiant energy, in which the parts are arranged according to their refrangibility or wave-length, so that all of the same wave-length fall together, while those of different wave-lengths are separated from each other, forming a regular progressive series.



The most common form of spectrum is that produced by the light of the sun passing through a triangular glass prism and falling on a screen. The component colors, being unequally refracted, are spread out into a band displaying the seven rainbow colors, having the red at one end (that of least deviation) and the violet at the other. The same effect is produced by reflection from or passage through a diffraction grating. (See DIFFRACTION.) Instead of being received on a screen, the spectrum may be viewed directly with a telescope. (See SPECTROSCOPE.) The spectrum is not limited to the visible part. There is an invisible spectrum below the red (the *infra-red spectrum*) and one above the violet (the *ultra-violet spectrum*), both of which can be detected by photography and by other physical processes. (See BOLOMETER.) Different media disperse the rays in varying degrees in different parts of the spectrum, while the gratings do not; hence the spectra due to refraction are called *abnormal*, and those due to diffraction *normal*. Solid and liquid bodies, when incandescent, give out *continuous* spectra; gaseous bodies give out *line*, *band*, or *fluted* spectra, according to the degree of their density. If light from an incandescent solid passes through gas at a lower temperature, or through some solids and liquids, some rays are absorbed, producing *absorption spectra*. See SPECTRUM ANALYSIS, and other phrases below.

2. An after-image. Called also *ocular spectrum*.

On looking for a time on the setting sun, so as not greatly to fatigue the sight, a yellow *spectrum* is seen when the eyes are closed and covered, which . . . disappears and recurs repeatedly before it entirely vanishes. ERASMUS DARWIN *Zoonomia* vol. I, § 12, class iv, pt. iii, p. 115. [J. J. '01.]

3†. An apparition. [L.; see SPECTER.]

Phrases:—absorption spectrum, the spectrum of the case of a gas correspond exactly in position with those of the emission spectrum it would produce if it were incandescent. In chemistry, substances to be analyzed are vaporized and heated to incandescence in a hot flame or in the electric arc, or, if they are to be examined by their absorption, are placed between the spectroscope and a bright light. Minute quantities that would evade chemical analysis can thus be detected easily and certainly. The spectra of celestial objects are examined with a special form of spectroscope attached to a telescope (see illus. in first column), and by the comparison of these with spectra of terrestrial substances it has been possible to prove the existence of such substances in the sun and stars. By observation of the shifting of the spectral lines, too, it is possible to measure the velocity of stars in the line of sight. (See DOPPLER'S PRINCIPLE, under PRINCIPLE.) Much labor has been spent upon determining the characteristic spectra of the chemical elements, their changes under varying physical conditions, their presence in the sun and the stars, the classification of stars, and their development by comparison of such changes. See STAR-TYPE.—**thermal s.,** same as HEAT SPECTRUM.

The Solar Spectrum.

1. A prismatic spectrum, showing 400 of the principal Fraunhofer's lines according to Van der Willigen, from the line *A* to the line *H*. See note under LINE, *n.*, 23 (2). Though the length is about the same as the colored prismatic spectrum shown in the plate, the dispersion is different, owing to differences in the prisms, as will be seen by comparing the positions of the lines. The space from *m* to *n* in this figure is represented on an enlarged scale in fig. 2, below. 2. A section of the solar spectrum, showing most of the dark (Fraunhofer's) lines between the wave-lengths 0.510 and 0.530 micron. The lines from 0.5162 to 0.5188 constitute what is known as the "*little b*" *group*, shown in the whole spectrum at *b*. The above section is 0.4 in. (1 cm.) in the plates of the whole spectra. (From a photograph by Prof. H. A. Rowland.)

Table of Colors.

In the following table the columns headed Bk, W, R, etc., contain the percentages of black, white, red, orange, yellow, green, and blue, respectively, that compose the color given in the first column. Under "remarks" are given approximate synonyms and definitions of unusual colors. The wave-lengths of the standard colors in microns are as follows: red, 0.644; orange, 0.614; yellow, 0.585; green, 0.521; blue, 0.475. To obtain the desired color, its components must be blended, not by mixing pigments, which will not give the proper result, but in the following manner: Seven standard disks must be prepared, each from 3 to 5 inches in diameter, with a small hole at the center for the axis and a radial cut from center to periphery. The white disk must be of the purest white cardboard; the others should be cut from light cardboard or heavy drawing-paper, and painted each with its proper color. For the black disk use a mixture of the best lampblack in a solution of shellac in alcohol, applying it with a bristle brush like an oil-paint. Experiment will show the proper proportions to leave the surface even, firm, and dull. The remaining 5 disks are to be painted respectively with the best English vermilion, mineral orange, light chrome yellow, emerald-green, and artificial ultramarine blue. The pigments should be mixed with a thick solution of gum arabic in water, to the consistency of oil-paint, and applied with a bristle brush. The color must be even and the paper completely covered.

To prepare any color from the equivalents given in the table, put the required disks upon the axis of any rotation-machine, as a color-wheel or color-top (see COLOR), with the edges of the slits so interposed that a sector of each disk is visible; then, by means of a cardboard circle divided on its edge into hundredths, arrange the relative proportions of the standard colors according to the formula given in the table. When the wheel or top is set in rapid rotation, the required color will result from the blending of the components.

In a few cases the colors are too brilliant to be matched with the disks; under these circumstances the brilliancy is reduced by blending with the color a certain percentage of black or white, as given in the first column; this modified hue is then matched by the formula given in the remaining columns; for example, 83 red and 17 blue will match rose lake blended with 30 parts of black. Colors shown in the colored plate are designated in this table by an asterisk, and often differ slightly from the most generally accepted hues of the same names, which are also given in most cases.

Phrases:—absorption spectrum, the spectrum of light that has undergone selective absorption by passing through a gas or other partially transparent medium; commonly characterized by dark lines showing the wave-lengths of the absorbed light.—**actinic s.,** a spectrum in which only the actinic rays are taken account of. Called also *chemical spectrum*.—**band s.,** a spectrum apparently composed of dark or bright bands, intense at one edge and fading off toward the other. Powerful instruments show that each band is made up of many fine parallel lines, very close together at one edge of the band, the distances apart regularly increasing toward the other. Absorption spectra show dark bands that can not be resolved into lines.—**chromatic s.,** a spectrum in which only the visible rays are taken account of, the different wave-lengths of the light being shown by their colors.—**continuous s.,** a spectrum in which the different colors fade into each other by insensible gradations, no lines or bands, whether dark or bright, being present.—**diffraction s.,** a spectrum produced by diffraction, especially by the reflection of light from or its passage through a diffraction grating.—**emission s.,** a spectrum regarded as characterizing the body that emits the rays rather than one through which they pass: opposed to *absorption spectrum*.—**fluted s.,** a spectrum in which the intensity of the light is so graduated that it appears as if transversely channeled or fluted.—**gaseous s.,** a spectrum formed from the rays emitted by an incandescent gas: generally consisting of a limited number of bright lines, separated by dark spaces.—**heat s.,** a spectrum in which only the heat effect is taken account of; especially, one formed by non-luminous radiant energy. Called also *thermal spectrum*.—**line s.,** a spectrum of isolated narrow lines, as of an incandescent vapor.—**normal s.,** a spectrum in which an exact geometric relation between the wave-length of the light and its position in the spectrum may be established; especially, a diffraction spectrum.—**ocular s.,** same as SPECTRUM, 2.—**prismatic s.,** the spectrum produced by the dispersion of light by a prism.—**solar s.,** the spectrum formed from the rays of the sun, an absorption spectrum characterized by thousands of fine dark lines, called Fraunhofer's lines, arranged in a large number of groups. See LINE, *n.*, 23 (2).—**s. analysis,** the science or process of inferring the chemical constitution of bodies from the spectra of the light that they emit or absorb; analysis by the spectroscope. A substance in the form of an incandescent gas may be identified by the arrangement and position of the bright lines in its spectrum, which are the same for every substance. Cool gases, and many liquids and solids, are recognized by the characteristic dark lines of their absorption spectra (see phrase), which in

Prismatic Solar Spectrum; showing position of Fraunhofer lines, and of the five simple colors.

Normal Solar Spectrum; showing position of Fraunhofer lines, and of the five simple colors.

Twenty-one colors forming an approximate normal spectrum

Solar Spectrum and Typical Colors.

48 Type colors with ordinary names: for composition see accompanying table. In the prismatic spectrum the dispersion is not proportional to the wave-length. In the grating or normal spectrum the dispersion is proportional to the wave-length. The letters A to H designate the Fraunhofer lines. The numerals I. to V. locate the five simple colors used in the accompanying table. The third spectrum is arbitrarily divided into 21 parts: red R, orange O, yellow Y, green G, blue B, violet V, and their intermediate colors.

sponge, *n.* **1.** An animal with pores in the body-wall and without tentacles; one of the *Porifera*.

The simplest known sponge is a vase-like sac attached

by its blind end, with an osculum at the free end, and has thin walls of which the endoderm or inner layer consists of collar-cells which resemble choanoflagellate infusorians. In the higher sponges the pores open into much-branched afferent canals passing to the ciliated chambers to which the collar-cells are restricted and from which efferent canals lead into the central cavity, this opening outward by the osculum. Water laden with food (minute organisms) enters the pores in a constant stream maintained by the action of the flagella of the collar-cells, and passes out with the waste particles by the osculum. Sponges live fixed to other objects or rooted in mud, and are mostly marine. Reproduction is asexual, by external or internal budding, or sexual, by eggs and spermatozoa. Skeletal structures or spicules, consisting of calcium carbonate, of silica, or of horn spongin, are formed in the mesoderm.

[< LL. *spontaneus*; see SPONTANEITY.]

Synonyms: automatic, instinctive, involuntary, unbidden, voluntary, willing. That is *spontaneous* which is freely done, with no external compulsion and, in human actions, without special premeditation or distinct determination of the will; that is *voluntary* which is freely done with distinct act of will; that is *involuntary* which is independent of the will, and perhaps in opposition to it; a *willing* act is not only in accordance with will, but with desire. Thus *voluntary* and *involuntary*, which are antonyms of each other, are both partial synonyms of *spontaneous*. We speak of *spontaneous* generation, *spontaneous* combustion, *spontaneous* sympathy, an *involuntary* start, an *unbidden* tear, *voluntary* agreement, *willing* submission. A babe's smile in answer to that of its mother is *spontaneous*; the smile of a pouting child wheedled into good humor is *involuntary*. In physiology the action of the heart and lungs is called *involuntary*; the growth of the hair and nails is *spontaneous*; the action of swallowing is *voluntary* up to a certain point, beyond which it becomes *involuntary*, or *automatic*. In the fullest sense of that which is not only without the will but distinctly in opposition to it, or compulsory, *involuntary* becomes an antonym, not only of *voluntary* but of *spontaneous*; as, *involuntary* servitude. A *spontaneous* outburst of applause is of necessity an act of volition, but so completely dependent on sympathetic impulse that it would seem frigid to call it *voluntary*, while to call it *involuntary* would imply some previous purpose or inclination not to applaud.

—**spontaneous generation**, the supposed production of living from not-living matter; abiogenesis: once supposed to be shown by the appearance of life in certain infusions, now known to be due to microorganisms, as bacteria. **s. suggestion** (*Psychol.*), suggestion in memory from the association of ideas without conscious volition.

stan'za, stan'za, *n.* **1.** *Pros.* (1) A group of rimed lines, properly four or more, usually forming one of a series of similar divisions in a poem; a part of a poem that ordinarily presents certain variations of measure or arrangements of rime repeated in the poem: distinguished from a poetic *verse*, which strictly is a single line.

Two rimed lines form a *couplet*, three a *triplet*. A four-lined *stanza* is often called a *quatrain*; a six-lined *stanza*, a *sestet*; an eight-lined *stanza*, an *octave*. Favorite stanzaic forms in English are the four-stress quatrain with alternate rimes, the rime royal in seven decasyllabic lines (a b a b b c c), the Spenserian in eight decasyllabic lines and an Alexandrine (a b a b b c b c c), the ottava rima of "Don Juan" and Keats's "Isabella" (a b a b a b c c), and the ode-stanza of Gray, Wordsworth, etc. The letters in the parentheses show the arrangement of rimes. Compare STROPHE. See also BALLADE; RONDEAU; RONDEL; SONNET; TERZA-RIMA; TRIOLET; VILLENNELLE.

(2) A classic meter or strophe such as the Alcaic or the Sapphic, in four lines or in couplets, and governed by the laws of quantity. See STROPHE; SYSTEM.

The prevailing method of combining verses is by end-rime; and here we distinguish between *stanzas* where the verses are homogeneous, and *stanzas* made up of verses with a varying number of accents. F. B. GUMMERE *Poetics* ch. 8, p. 235. [G. & CO. '91.]

The alexandrine was, I believe, first used by Spenser, for the sake of closing his *stanza* with a fuller sound. S. JOHNSON *Lives of the Poets, Dryden* in vol. i, p. 306. [S. E. '10.]

The number of fixed stars distinguishable to the naked eye is from four to six thousand; but the largest telescopes reveal probably between 30 and 50 millions. The brightness of stars is expressed by a scale of magnitudes in which the 16 brightest are called of magnitude 1, and the faintest visible to the naked eye of magnitude 6. Several hundred of the brighter stars are designated by the name of the constellation to which they belong, preceded by a Greek or Roman letter or number. Of these many also have special names of their own, generally assigned by the Arabian astronomers, as shown in the table below. Classified by their spectra, stars fall under several types. See STAR-TYPE, below. Compare ASTEROID; CONSTELLATION; PLANET.

The granules differ in size and appearance according to the source, ranging in diameter from .002 millimeter to .185 millimeter, and thus the various kinds of starch may be distinguished in commerce. Starch is an exceedingly important constituent of vegetable foods. Rice contains 76 per cent. of it; maize, 56; wheat, 54.75; barley, 46.3; rye, 45; beans, 37.7; oats, 36.5; and potatoes, 18.5. The action on starch of certain enzyms, as ptyalin of the saliva and amylopsin of the pancreatic juice, is of great value in digestion, yielding maltose and dextrin. In brewing starch is converted into maltose by the diastase of the barley-grains. Thousands of tons of starch are annually converted into glucose, and also into dextrin or British gum, by treating it with heat and mineral acids. The names of different kinds commonly indicate the source; as, **arrowroot-starch, corn-s.** or **maize-s., lichen-s., potato-s., rice-s., tapioca-s., wheat-s.**

2. A political community organized under a distinct government recognized and conformed to by the people as supreme: a commonwealth; a nation.

There is usually regarded as essential to a state, association, organization, civil government, and ordinarily a common place of abode for its members. Though actually growing out of the family, it has a natural basis in man's social nature and relations, a form decided by men connected with it, and a legal basis and standard of ultimate appeal in essential right and justice. Its chief aim is to widen man's sphere of social effort and activity and to insure freedom and security in that sphere.

The American Union constitutes the real American *State*. Our commonwealths have only a limited sovereignty, and are imperfect *States* in the real sense of the word *State*; they are only parts of a great *State*. R. T. ELY *Intro. to Polit. Econ.* pt. i, ch. 3, p. 30, note. [CHAUT. '89.]

Most of the latter had previously been governed as Territories. (See TERRITORY.) In most of the republics modeled after the United States, as in South America, the states are somewhat arbitrary divisions of the country made after the independence of the whole country had been achieved. A State of the United States has its own legislature, executive (called a *governor*), and courts, and manages its own affairs with the exception of such as are delegated to the federal government, as foreign relations, interstate commerce, the currency, etc. Compare FEDERAL.

[< AS. *stelan*, steal.]

Synonyms: abstract, commit larceny, commit theft, embezzle, extort, filch, pilfer, pillage, plunder, purloin, rob, swindle. To *commit larceny* is to take and carry away the personal property of another with felonious intent. To *commit theft* (more commonly with the indefinite article, to *commit a theft*), has the same general meaning, but is not a common phrase in legal use. To *steal* is, in law, to *commit* simple *larceny;* but the word may be applied to any furtive, covert, or surreptitious taking of anything, whether material or immaterial. To *pilfer* is to *steal* petty articles. The word *filch* especially emphasizes the secrecy and slyness of the act; *filch* is ordinarily applied to things of little value, but may apply to the most precious, as in Shakespeare, "he that *filches* from me my good name." To *purloin* is etymologically to carry far away, and is commonly applied to the dishonest removal of articles of value or importance. To *rob* is, in law, to take feloniously from the person by force or fear, as in highway robbery; in a more extended use it is applied to the felonious taking of articles of value from places as well as persons, generally with suggestion of force and violence. To *abstract* is to take secretly and feloniously from among other things belonging to another. To *embezzle* is to appropriate fraudulently to oneself funds received and held in trust. To *swindle* is to cheat grossly, commonly by false pretenses, but is not a recognized legal offense under that name; one form of *swindling*, the "obtaining money by false pretenses," is an indictable offense, but much *swindling* may be carried on under the forms of law. To *plunder* is to take property from an enemy in time of war, and is not a crime at law. See ABSTRACT.—**Antonyms:** give back, give up, make good, refund, repay, restore, return, surrender.

steam, *n.* **1.** Water in the form of vapor; aqueous vapor; especially, the gas into which water is changed by boiling: transparent until it begins to condense.

Water changes into aqueous vapor by surface evaporation at all temperatures, but the vapor is not commonly called *steam* till it is produced in the body of the liquid by ebullition. The temperature at which this takes place increases with the pressure; at ordinary atmospheric pressure it is 100° C. or 212° F. The temperature is influenced also by impurities in the water and by the substance of the containing vessel. When ebullition begins, the water remains at the same temperature, all the heat applied being employed in doing molecular work in changing water into steam. This fact is expressed in ordinary language by saying that the heat becomes *latent* in the steam. On condensation the heat reappears. Till the moment when all the water is turned into steam, the latter is said to be *saturated*. If heated still more, its temperature rises and the steam is said to be *superheated*. (See phrases below.) Steam is the most economical agent known for use in engines, on account of its great latent heat, coefficient of expansion, and facility of condensation. (See ENGINE; STEAM-ENGINE.) It is used largely for heating, chiefly for warming buildings, but also for cooking, and in various manufactures, as in brewing.

Steam is used as the first element of many compound words which are self-explaining in the sense of operated by steam-power; as, **s.-brake, s.-capstan, s.-crane, s.-dredger, s.-excavator, s.-hoist, s.-launch, s.-packet, s.-tug, s.-vessel, s.-wagon, s.-winch, s.-windlass, s.-yacht.**

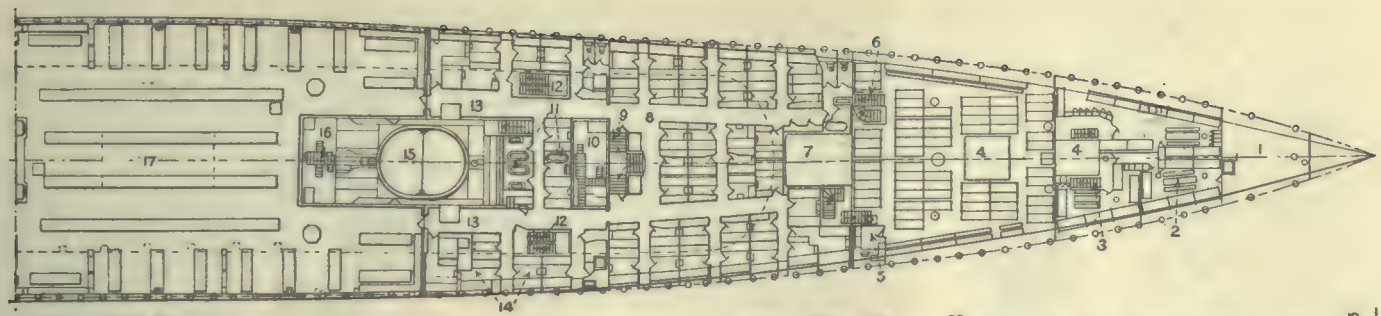
steam'en"gin(e, stīm'-en'jin, *n.* An engine that derives its motive force from the action of steam, commonly by confining it and utilizing the pressure; a form of heat-engine in which steam is the working fluid.



It is made in a great variety of forms, but includes ordinarily a *boiler* for generating the steam (though the boiler is usually considered as a separate device) with a *steam-chest*, enclosing a *slide-valve* or other distributing-valve or -valves, in connection with *steam-ports* for regulating the flow of steam alternately to each end of a *cylinder* containing a *piston*, and for putting the other end in communication either with another working cylinder, or with the outside air, or with a condenser. The to-and-fro motion of the piston thus caused operates a crank, and renders the force available for driving machinery. A steam-engine is **stationary** when mounted in fixed and permanent form, **portable** when mounted with the boiler on wheels, so as to admit of being moved about to any point where the power is to be utilized, **semiportable** when of small size, with the engine arranged as a fixture on top of the boiler, and **locomotive** when furnishing power to move itself about and to draw a load. See LOCOMOTIVE, list under ENGINE, and illus. under MARINE ENGINE.

ment to a boiler, having mechanism by which the steam turns a pointer on a dial bearing figures, showing the pressure in pounds to the square inch. The most common varieties use either a spring or a column of mercury to act against the pressure, and in either case are connected with the boiler by a bent tube for holding water to prevent steam reaching the gage.

—**thermometric steam-gage,** a gage that shows steam-pressure by the degree of expansion of a liquid, as mercury, caused by the heat of the steam; a thermometer graduated to show pressure of saturated steam per unit of area instead of or in addition to degrees of temperature.

steam'-ham"mer, stēm'-ham'ėr, *n.* **1.** A powerful machine-hammer in which a steam-cylinder mounted between guides delivers a downward blow with a ram attached to its piston, so that the impulse of the steam and the weight of the moving parts may act together in one direction, though often the steam is used only to raise the piston and ram, which are allowed to fall by their own weight. The height of the fall and the force of the blow can be regulated at will. The steam-hammer is used for the largest forgings, though capable of the most delicate work. It was invented by James Nasmyth of Edinburgh (1808–'90), in 1838.

iron (chiefly with carbon) that is decidedly malleable at some high temperature: including most common alloys of iron that are neither distinctly wrought iron nor cast iron. Specifically: (1) A compound of iron containing 0.25 to 3 per cent. of carbon, usually with small quantities of silicon and manganese; normal steel. The carbon causes it to harden intensely when cooled suddenly from a red heat and to soften again when cooled slowly. For a given size it is the strongest material known. Most of this steel is classed as **harder** or **ingot steel,** and is so made by a fusion process as to be free from intermingled slag. It is the best-known class of steel. From it are made cutting-tools and springs of all kinds, dies for stamping and engraving, rails, and railway-tires. Formerly nearly all armor and ordnance were made of it. **carbon steel‡.** (2) A compound of iron containing less carbon than normal steel, and therefore not hardening so intensely, if at all, when cooled suddenly. Called distinctively **soft steel.** Soft steel differs from wrought iron in being so made by a fusion process that it is free from slag. Steel boiler-plates and tubes, I beams and structural pieces, shafting, ship-plates, rivets, nails, and tin-plate are usually made from it. **ingot iron‡.** (3) Alloy steel. See phrase below. Varieties are named also from the degree of carburization; as, **hard s., mild s.,** etc.; and the method of production; as, **Bessemer s.** (see BESSEMER), **crucible s., open-hearth s.**

I conceive it [steel] to consist (A) of a matrix of iron which is sometimes (as in ingot-iron and annealed *steel*) comparatively, or even quite pure, and sometimes (as in hardened *steel*, manganese *steel*, etc.) chemically combined with a portion, or even the whole of the other elements which are present, probably in indefinite ratios, its mechanical properties being greatly affected by them: and (B) of a number of independent entities which we may style 'minerals,' chemical compounds of the elements present, including iron, which crystallize within the matrix, and by their mechanical properties, shape, size, and mode of distribution, also profoundly affect the mechanical properties of the composite mass, though probably less profoundly than do changes of corresponding magnitude in the composition of the matrix. (3) A steel strip for stiffening a corset; a corset-steel. (4) A piece of steel for use in striking fire with a flint. (5)† A mirror. [< AS. *stȳle*, steel.]

Phrases, etc.:—alloy steel, an alloy of iron with metal, as chromium, manganese, or nickel, which imparts certain properties to the alloy. The alloy steels contain about one per cent. of carbon and are habitually so made by fusion as to be free from slag. They include **chromium s.** (containing about 2 per cent. of chromium), an alloy that hardens intensely on sudden cooling, and is used for the manufacture of armor-piercing projectiles, safe-plates, and crushing-machinery; **nickel s.** (containing about 3 per cent. nickel), combining great strength with great ductility and non-fissility, and used for the best armor-plates; **manganese s.** (containing about 12 per cent. of manganese), a non-fissile alloy that exceeds all other known materials in its combination of hardness and ductility; used chiefly where resistance to abrasion is required, as in crushing- and dredging-machinery, and in some car-wheels; and **tungsten s.** (containing from 6 to 10 per cent. of tungsten), an extremely hard alloy which does not lose its hardness by friction with iron, and is hence used for iron-cutting tools and for magnets.—**bronze s.,** an alloy of copper, tin, and iron: used as gun-metal.—**carbon s.,** ordinary steel, as distinguished from chrome steel, manganese steel, etc.—**cast s.,** any malleable compound of iron produced by fusion, including both Bessemer and open-hearth steel, as well as crucible steel.—**cement s.,** steel made by cementation; blister-steel.—**chrome** or **chromium s.,** steel having a small proportion of chromium, very hard and malleable, but rusting easily.—**crucible s.,** steel made in crucibles; a fine kind of cast steel.—**German s.,** a metal made from charcoal iron obtained from bog-iron or from sparry carbonate.—**high s.,** steel containing a large proportion of carbon.—**homogeneous s.,** cast steel without blow-holes.—**India s.,** a fine natural steel from southern India made direct from the ore; wootz.—**low s.,** steel poor in carbon, and hence comparatively tough and soft, and usually not susceptible of hardening or tempering. **mild s.‡; soft cast s.‡; structural s.‡.**—**ma-chin'er-y-steel",** *n.* Steel suitable for making parts of machinery but not for cutting-tools.—**native s.,** a steel or steely iron occurring in small masses and made by the ignition of coal near an iron-ore deposit.—**run s.** [Eng.], cast steel.—**special s.,** steel in which another element than carbon gives the characteristic hardness, as chrome or nickel steel.—**steel'-clad",** *a.* Clothed with steel; clad in armor; armored.—**s.-duck,** *n.* [Prov. ster'e-o-scope, ster'ę-o-scōp, *n.* **1.** *Physics.* An optical instrument for blending into one image two pictures of an object from slightly different points of view, so as to produce upon the eye the impression of relief. The stereoscopic effect may be produced by simply placing a card between the eyes, also by reflecting the pictures by mirrors to the eye, and more commonly by an adjustment of two lenses.

The Principle of the Stereoscope.

The two outlines in fig. 1 show an object in relief, the left one as it appears to the left eye, and the right one as it appears to the right eye. Their combination gives a sensation of actual solidity, as can be shown by copying them on a larger scale and holding a card between them, so that they can be viewed simultaneously each with its appropriate eye. If the two figures be exchanged, the resulting image will appear hollow instead of in relief. Fig. 2 shows the use of the card. The eyes, looking along *L l* and *R r* respectively, combine the images of the points *l* and *r* at *o*. Without the card (represented by the dotted lines), *l* will be seen also along the line *Rl*, and *r* along *Lr*, so that there will be three images; the card shuts off the two latter.
